

Introduction to Scientific Computing II

Lecture 3

Amir Farbin

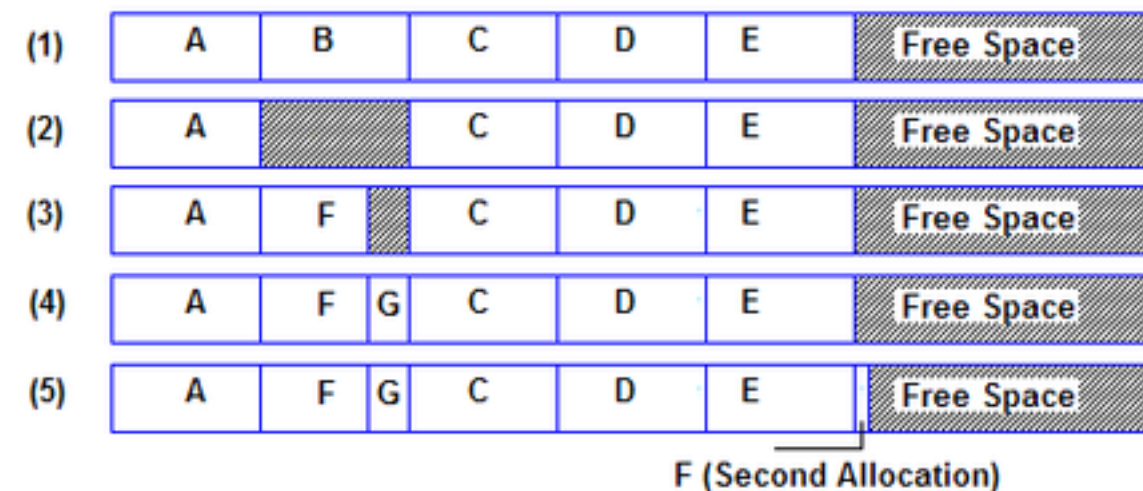

- 1. Storage, Filesystem**
- 2. Firmware → Operating System → Apps**
- 3. Machine Language → Python**

Storage

- Storage devices provide an interface to read / write data into specific locations of some in non-volatile media.
 - On traditional **Hard Drive**, the data is written magnetically on a spinning metal disk.
 - The disk is divided up into sectors, the minimum storage unit.
 - Each sector has an address, which corresponds its physical location on the disk.
 - **Solid State Drives** store data on silicon... originally presented same interface as HDs, but new interfaces such as non-volatile memory express (NVMe) are designed for SSDs.
 - In Unix these are referred to as: /dev/hda, /dev/hdb, ... /dev/sda, /dev/sdb
- **Partition**: The disk sectors are partitioned into groups of sectors, each where a different file system can be created.
 - Partition table: keeps track of the locations of the partitions.
 - /dev/hda1, /dev/sdb2
 - Partitions can be further divided into logical partitions.

File system

- File system is a scheme for controlling how data is stored and retrieved from a partition.
 - File system organizes the sectors into blocks.
 - Organization:
 - Data is grouped into files.
 - Files have meta-data: e.g. when created, access permissions, ...
 - Files are organized into directories.
 - FS holds a map Files names → Blocks.
 - Different file systems have different restrictions file names (e.g. allowed characters or case sensitivity).
 - General convention, “FOO.BAR”, FOO is filename, BAR is the extension which helps indicate the format of the file contents.
 - FS enforce Access Control or Permissions... who can read what file.
 - Different File system types:
 - Windows: FAT (FAT16, FAT32), exFAT NTFS, ...
 - Mac: HFS, HFS+, APFS
 - Unix: ext2, ext3, ext4, ZFS, ...
 - SWAP: In some Operating Systems, the system can use storage as RAM when out of memory.

Software- Firmware

- There are several layers of software that interact with the computer at different levels.
 - During system boot, system starts with the Firmware, and hands control to next level, which then hands control on to then next level, and so on ...
- **Firmware:** Associated with the motherboard. Read Only Memory (ROM).
 - When you start a computer, it needs some instructions on what to do.
 - Test that everything is OK... e.g. memory.
 - Load user configuration.
 - Allow users to change configuration via menu system.
 - Start and configure peripherals, storage, ...
 - Load the boot loader from storage into memory and hand-off
 - In the x86 world:
 - Basic Input/Output System (BIOS): Old
 - Unified Extensible Firmware Interface (UEFI): New

Boot Loader ...

- Small program that loads the operating system kernel.
- Loaded by the firmware.
- Usually sits on the first sectors of the storage boot drive.
- May give the user the option of loading different operating systems sitting on different partitions of the storage.
- Must mount the partition, find the kernel (operating system), load it into memory, pass control to the kernel with potentially some configuration options (e.g. the root partition).

Operating System

- Software system that manages the computer hardware and software and provides common services for programs.
 - Sharing of resource between programs: processor, memory, storage, ...
 - Intermediary between programs and hardware.
 - Provides Application Program Interface (API) / Software Development Kit (SDK) for building programs and interfacing them with OS.
- Examples: Windows, MacOS, Linux, iOS, Android, ...
- Modern OSs are Multi-tasking: allow multiple programs to simultaneously run.
 - Each program ~ a process.
 - Pre-emptive multitasking: the OS gives slice of CPU time to each process.

Unix

- Multitasking, Multi-user, OS originally developed in 1970 by AT&T Bell Labs to run on mainframes with many connected terminals.
 - Written in C programming language.
- Many modern operating systems, including MacOS and Linux, implement Unix standards.
- “Unix Philosophy”
 - Plain text data storage.
 - Hierarchical file system.
 - Devices and inter-process communication via files
 - Main program that runs is the *kernel*.
 - Primary user interface is a *command-line* interpreter, called a shell.
 - Modular:
 - lots of small programs serve as tools
 - strung together via the *command-line* interpreter
 - passing information between each other via pipes

Graphical User Interface

- Though most of you associate an OS with its GUI, it is generally a layer on top of the core OS.
 - Establishes graphical metaphors aimed at simplifying user interaction with the OS.
 - Mouse cursor, windows, menus, buttons, ...
 - Provides API for applications to build GUIs for themselves.
- For Unix, the X Windows system implements a client-server model:
 - The server runs the application that makes the API GUI calls.
 - These calls are transmitted to the network to a client.
 - The client runs the graphical environment, collects input, and draws the graphical elements.

Programming

- Each CPU understands its own instruction sets.
- Low level operations:
 - Copy in/out data from memory into registers.
 - Perform operations on registers.
 - Conditional (if/then) and Control flow (jump)
 - Manage a stack (where small sets of data can be shared between different blocks of code)
- Each instruction are each assigned a specific binary value and are not human readable...
- Assembly is a human-read language that most closely mirrors Machine Language.

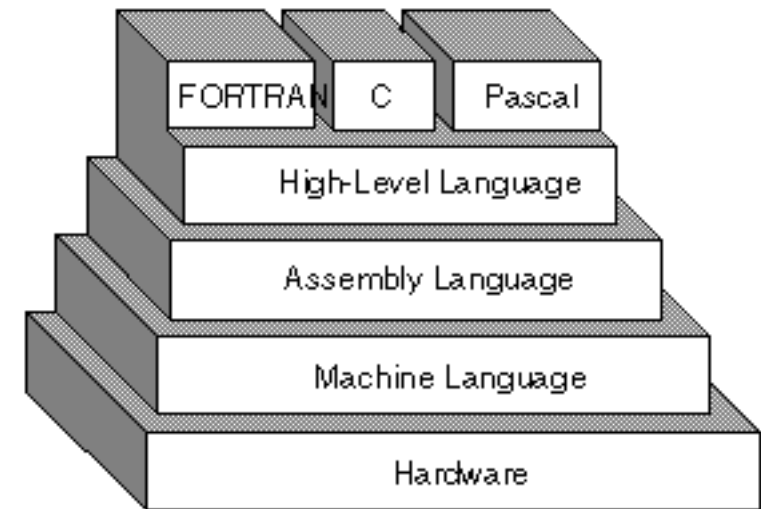

```
x3000 LD R1, x006           ; load data pointer
x3001 LDR R2, R1, #0         ; load data value
x3002 BRz x005             ; branch to end if zero
;
; repeating statements go here
;
x3003 ADD R1, R1, #1         ; increment data pointer
x3004 BRnzp x001           ; branch back to top
x3005 HALT
;
; data section
;
x3006 x4000 ; address of data

; The translation into LC-2 Machine Code
0011 0000 0000 0000        ; load at x3000
x3000 0010 001 0 0000 0110 ; LD R1, x006
x3001 0110 010 001 000000   ; LDR R2, R1, #0
x3002 0000 010 0 0000 0101 ; BRz x005
;
; repeating statements go here
;
x3003 0001 001 001 1 00001  ; ADD R1, R1, #1
x3004 0000 111 0 0000 0001 ; BRnzp x001
x3005 1111 0000 0010 0101   ; HALT
;
; data section
;
x3006 0100 0000 0000 0000   ; x4000
```

Programming Languages

- Writing Assembly (Machine) code requires
 - knowledge of the specific CPU,
 - working at level of very small operations and
 - awareness of registers, memory, and hardware.
- High-level languages provide high level abstractions and human friendlier syntax for programming.
- Two types:
 - **Compiled:** The text of the high level language is converted by a *compiler* into machine code. The machine code is run subsequently. Usually 2 steps:
 1. Compile to code into machine language → library
 2. Link the code against libraries → executable
 - **Interpreted:** A program runs that reads the text of the high level language and performs the operations.

High-level Language

- 3 Fundamental Elements of any programming language:

1. Primitives:

- Numbers, Characters, ...
- Mathematical Operations: +, -, *, /, ...
- Logical Operations: and, or, ...
- Conditionals: if-then-else, ...

2. Means of Combination: e.g. list

3. Means of Abstraction:

- Assignment: `x = 1`
 - Definition: `def x: 1`
 - Function: `def f(x): x`
- Beyond these, there are universal programming concepts and patterns (e.g. object oriented programming) that enable or facilitate building sophisticated software.
 - While we will learn these in python, look beyond the syntax and specifics of the programming language.

Why Python?

- Interpreted: no compilation time. Multi-platform.
 - Expense of speed, but the time consuming code are often in complied libraries.
- Large library: almost any package out there has a python API.
- Easy to read. Convenient syntax.
- Convenient data structures that are simple to build.
 - Advanced data structures: list, dictionaries, sets...
 - Dynamic typing: no need to declare the type of a variable.
 - Built-in memory management (reference counting + garbage collection): No need to worry about memory addresses or allocating/freeing memory.
 - Dynamic name resolution (late binding): same code can be reused for different data.
- Multi-paradigm:
 - structured programming: functions, sub-routines, etc...
 - functional programming: filter, map, reduce, lambda, generators, ...
 - object-oriented programming: class, inheritance, ...
 - ...
- Language of choice for Data Science.
